

Class 13

Erin Li

2023-11-14

This week we are looking at differential expression analysis.

The data for this hands-on session comes from a published RNA-seq experiment where airway smooth muscle cells were treated with dexamethasone, a synthetic glucocorticoid steroid with anti-inflammatory effects (Himes et al. 2014).

Import/Read the data from Himes et al.

```
counts <- read.csv("airway_scaledcounts.csv", row.names=1)
metadata <- read.csv("airway_metadata.csv")
```

```
head(metadata)
```

```
##           id      dex celltype    geo_id
## 1 SRR1039508 control  N61311 GSM1275862
## 2 SRR1039509 treated  N61311 GSM1275863
## 3 SRR1039512 control  N052611 GSM1275866
## 4 SRR1039513 treated  N052611 GSM1275867
## 5 SRR1039516 control  N080611 GSM1275870
## 6 SRR1039517 treated  N080611 GSM1275871
```

Sanity check on correspondence of counts and metadata

```
all(metadata$id==colnames(counts))
```

```
## [1] TRUE
```

Q1. How many genes are in this dataset? There are `nrow(counts)` genes in this dataset.

Q2. How many 'control' cell lines do we have?

```
n.control <- sum(metadata$dex == 'control')
n.control
```

```
## [1] 4
```

There are `n.control` control cell lines in this dataset.

```
control <- metadata[metadata[, "dex"]=="control",]
control.counts <- counts[, control$id]
control.mean <- rowSums( control.counts )/4
head(control.mean)
```

```
## ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
##           900.75           0.00           520.50           339.75           97.25
## ENSG00000000938
##           0.75
```

Q3. How would you make the above code in either approach more robust? Is there a function that could help here? Dynamic Count of Control Samples: Instead of hardcoding the divisor as 4 in `rowSums(control.counts)/4`, we can dynamically calculate the number of control samples. This ensures the code remains accurate even if the number of control samples changes.

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called `treated.mean`) ## Extract and summarize the treated (i.e. drug) samples

```
treated <- metadata[metadata$dex == "treated",]  
treated.counts <- counts[,treated$id]  
treated.mean <- rowMeans(treated.counts)
```

Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

```
meancounts <- data.frame(control.mean, treated.mean)  
plot(meancounts[,1], meancounts[,2])
```

Q5 (b). You could also use the

ggplot2 package to make this figure producing the plot below. What `geom_?()` function would you use for this plot? `geom_point()`

```
library(ggplot2)  
  
ggplot(meancounts) +  
  aes(control.mean, treated.mean) +  
  geom_point()
```

Q6. Try plotting both axes on a log

scale. What is the argument to plot() that allows you to do this? log='xy'

We will make a log-log plot to draw out this skewed data and see what is going on

```
plot(meancounts[,1], meancounts[,2], log='xy',
     xlab="log control counts",
     ylab="log of treated counts")
```

```
## Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
## from logarithmic plot
```

```
## Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
## from logarithmic plot
```

```
meancounts$log2fc <- log2(meancounts$treated.mean/meancounts$control.mean)
```

```
head(meancounts)
```

```
##          control.mean treated.mean      log2fc
## ENSG00000000003      900.75      658.00 -0.45303916
## ENSG00000000005         0.00         0.00         NaN
## ENSG000000000419      520.50      546.00  0.06900279

## ENSG000000000460       97.25       78.75 -0.30441833
## ENSG000000000938        0.75        0.00      -Inf
```

```
zero.vals <- which(meancounts[,1:2]==0, arr.ind=TRUE)
```

```
to.rm <- unique(zero.vals[,1])
mycounts <- meancounts[-to.rm,]
head(mycounts)
```

```
##          control.mean treated.mean      log2fc
## ENSG00000000003      900.75      658.00 -0.45303916
## ENSG000000000419      520.50      546.00  0.06900279
## ENSG000000000457      339.75      316.50 -0.10226805
## ENSG000000000460       97.25       78.75 -0.30441833
## ENSG000000000971      5219.00     6687.50  0.35769358
## ENSG00000001036     2327.00     1785.75 -0.38194109
```

Q7. What is the purpose of the `arr.ind` argument in the `which()` function call above? Why would we then take the first column of the output and need to call the `unique()` function? The `which()` function in R is used to identify the indices of elements that meet a certain condition in an array or matrix. `arr.ind=TRUE` is used to obtain both row and column indices of zeros in the first two columns of `meancounts`. The unique row indices where zeros occur are then extracted to identify which rows (likely corresponding to genes) should be removed from the dataset, as these rows contain zero counts in at least one of the samples and might not be informative for further analysis.

Q8. Using the `up.ind` vector above can you determine how many up regulated genes we have at the greater than 2 fc level? 250 Q9. Using the `down.ind` vector above can you determine how many down regulated genes we have at the greater than 2 fc level? 367 Q10. Do you trust these results? Why or why not? We will not fully trust, We have not done anything yet to determine whether the differences we are seeing are significant. These results in their current form are likely to be very misleading.

```
up.ind <- mycounts$log2fc > 2
sum(up.ind)
```

```
## [1] 250
```

```
down.ind <- mycounts$log2fc < (-2)
sum(down.ind)
```

```
## [1] 367
```

Q12. Can you do the same procedure as above to plot the pathview figures for the top 2 down-regulated pathways?

```
# Extract the top 2 down-regulated pathway IDs
top_down_pathways <- head(names(keggres$less), 2)

# Plot pathview for each of the top 2 down-regulated pathways
for(pathway in top_down_pathways) {
  pathview(gene.data = foldchanges, pathway.id = pathway)
}
```
